

Generalized Linear Models

Want a model for $(Y|X_1, \dots, X_p)$.

1. Specify a **family of distributions**.

2. Specify a **link function** $g()$ such that:

$$g\{E(Y|X_1, \dots, X_p)\} = \beta_0 + \beta_1 X_1 + \dots + \beta_p X_p.$$

Note: $\eta = \beta_0 + \beta_1 X_1 + \dots + \beta_p X_p$ referred to as **linear predictor**.

$> \text{glm}(y \sim x, \text{family} = \dots, \text{link} = \dots)$

1

Variance function and scale parameter

Write $\mu = E(Y)$ (so link function links μ to predictors).

Choice of distribution will lead to $\text{Var}(Y) = \phi v(\mu)$ for some **scale parameter** ϕ and **variance function** $v()$ describing the *mean-variance relationship*.

Sometimes ϕ is known, sometimes a nuisance parameter to be estimated.

Normal: $v(\mu) = 1$, ϕ unknown

Bernoulli: $v(\mu) = \mu(1 - \mu)$, $\phi = 1$.

Poisson: $v(\mu) = \mu$, $\phi = 1$.

3

Three primary examples:

$Y \sim N(\mu, \sigma^2)$, $\mu = \beta_0 + \beta_1 X_1 + \dots + \beta_p X_p$.

$Y \sim \text{Bernoulli}(p)$, $\text{logit}(p) = \beta_0 + \beta_1 X_1 + \dots + \beta_p X_p$.

Note: Binomial data can be treated as Bernoulli data. (Some issues lurking here - what is sample size? also deviance.)

$Y \sim \text{Poisson}(\lambda)$, $\log \lambda = \beta_0 + \beta_1 X_1 + \dots + \beta_p X_p$.

Note: Have given the ‘default’ link function in each case. This is more than convention, tied up with “exponential family” theory - the **canonical link function** is that which equates the **natural parameter of the distribution** with the **linear predictor**.

Other links sometimes used in Bernoulli case: probit $\Phi^{-1}(p)$, complementary log-log: $\log\{-\log(1 - p)\}$.

2

Computation (say ϕ known):

Distribution + link = fully-specified prob. model. Gives log-likelihood function $l(\beta)$.

NR algorithm to maximize $l()$, requires evaluation of $l'()$ and $l''()$.

Fisher-scoring modification: Replace $l''()$ with $E_{Y|X}\{l''()\}$.

Turns out we have an **iteratively reweighted least squares** (IRLS) algorithm.

Important/curious property. **Algorithm turns out to be 100% determined by data, link function, and variance function.** That is, choice of distribution only matters in terms of variance function it yields, also ϕ doesn't matter.

4

Gives strategy for add-on estimation of ϕ when needed. Pretend $\phi = 1$ and get $\hat{\beta}$, then **deviance** (recall defn, D_M in text). Then estimate $\hat{\phi} = (n - p)^{-1} D_M$.

Rationale: real/scaled/residual deviance is $\phi^{-1} D_M$.

Also, the role of the variance function leads to **quasi-likelihood** ideas: choose a variance function as one sees fit, don't worry if it corresponds to a real probability model or not.

5

So, have a general regression strategy for multiple types of Y variable.

Point estimation.

SE / Interval estimation.

6

Hypothesis testing: nested, q predictors versus p predictors.

Hypothesis testing: general goodness-of-fit (p predictors versus saturated).

Residual-based diagnostics

7

Poisson regression example

Deaths from coronary heart disease in a (famous) cohort study...

	Smokers		Non-smokers	
age	deaths	person-years	deaths	person-years
35-44	32	52407	2	18790
45-54	104	43248	12	10673
55-64	206	28612	28	5710
65-74	186	12663	28	2585
75-84	102	5317	31	1462

8

```
glm(formula = deaths ~ I(log(pyears)) + age.grp + smoke,
     family = poisson, data = dat)
```

	Estimate	Std. Error	z value	Pr(> z)
(Intercept)	-21.4739	2.2556	-9.520	< 2e-16 ***
I(log(pyears))	2.4352	0.2270	10.727	< 2e-16 ***
age.grp	1.7702	0.1542	11.478	< 2e-16 ***
smoke	-1.6991	0.3548	-4.789	1.68e-06 ***

Null deviance: 644.269 on 9 degrees of freedom
Residual deviance: 25.576 on 6 degrees of freedom

9

```
glm(formula = deaths ~ offset(log(pyears)) + age.grp +
     smoke,
     family = poisson, data = dat)
```

	Estimate	Std. Error	z value	Pr(> z)
(Intercept)	-7.28250	0.12076	-60.304	< 2e-16 ***
age.grp	0.83583	0.02904	28.777	< 2e-16 ***
smoke	0.40637	0.10720	3.791	0.00015 ***

Null deviance: 935.067 on 9 degrees of freedom
Residual deviance: 69.182 on 7 degrees of freedom

10

```
glm(formula = deaths ~ offset(log(pyears)) +
     age.grp + I(age.grp^2) + smoke,
     family = poisson, data = dat)
```

	Estimate	Std. Error	z value	Pr(> z)
(Intercept)	-7.93363	0.16395	-48.391	< 2e-16 ***
age.grp	1.70594	0.12824	13.303	< 2e-16 ***
I(age.grp^2)	-0.19438	0.02715	-7.159	8.14e-13 ***
smoke	0.35452	0.10737	3.302	0.00096 ***

Null deviance: 935.067 on 9 degrees of freedom
Residual deviance: 12.176 on 6 degrees of freedom

11

```
glm(formula = deaths ~ offset(log(pyears)) + age.grp +
     I(age.grp^2) + smoke + smoke:age.grp,
     family = poisson, data = dat)
```

	Estimate	Std. Error	z value	Pr(> z)
(Intercept)	-8.61296	0.29172	-29.524	< 2e-16 ***
age.grp	1.98113	0.16025	12.363	< 2e-16 ***
I(age.grp^2)	-0.19768	0.02737	-7.223	5.08e-13 ***
smoke	1.13342	0.28077	4.037	5.42e-05 ***
age.grp:smoke	-0.30755	0.09704	-3.169	0.00153 **

Null deviance: 935.0673 on 9 degrees of freedom
Residual deviance: 1.6354 on 5 degrees of freedom
